Light & Distance Table of Constants

Constants and Conversion Factors	
Speed of light	$c = 3.00 \times 10^8$ m/s $= 3.00 \times 10^5$ km/s
Astronomical unit (Earth to Sun)	1 AU $= 1.496 \times 10^{11}$ m
Light-year	1 ly $= 9.46 \times 10^{15}$ m
One year	1 yr $= 3.16 \times 10^7$ s
Parsec	1 pc = 206,265 AU $= 3.09 \times 10^{16}$ m = 3.26 ly
Diameter of the Sun	$D_\odot = 1.39 \times 10^9$ m (radius 6.96×10^8 m)
Earth to Moon (average)	3.84×10^8 m = 384,400 km

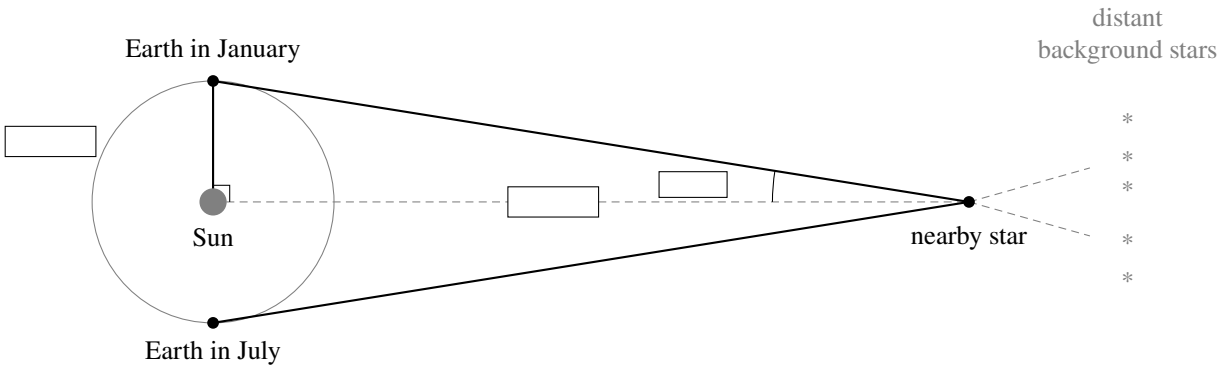

Angles	
Degrees and radians	$180° = \pi$ rad
Arcminutes and arcseconds	$1° = 60'$, $1' = 60''$, $1° = 3600''$
One radian	1 rad $= 57.3° = 3438' = 206{,}265''$

Equations	
Distance traveled by light in time t	$d = ct$
Echo (there and back in time t)	$d = ct/2$
Right triangle, legs x, y, hypotenuse h	$h^2 = x^2 + y^2$
Arc length on a circle of radius r	$a = r\theta$ (θ in radians)
Small angle: object of size D at distance d	$\theta \approx D/d$ (θ in radians)
Parallax angle p (page 2)	$p \approx$ _____ (p in radians)
Distance in parsecs	d [pc] = _____ (p in arcseconds)

Discover Parallax

Six months apart, Earth sees a nearby star from opposite sides of the Sun. The parallax angle p is the angle at the star between the Sun and Earth. Over six months the star seems to shift back and forth by a total angle of $2p$. The diagram is not to scale.

1. Fill in the three boxes on the diagram: the baseline from the Sun to Earth, the distance d from the Sun to the star, and the parallax angle p.

2. Look at the right triangle formed by the Sun, Earth in January, and the star. Write $\tan p$ in terms of 1 AU and d.

$$\tan p = _____$$

3. The parallax angle p is tiny. Use the small-angle approximation to find p in terms of 1 AU and d.

$$p \approx _____ \qquad (p \text{ in radians})$$

4. Convert to arcseconds with 1 rad = 206,265″ and 1 pc = 206,265 AU. Show that the distance in parsecs is

$$d\,[\text{pc}] = _____ \qquad (p \text{ in arcseconds})$$
